# One View, All Properties

Connect Your Portfolio Without Ripping Out Systems

---

databender.co | Data & AI Consulting for Growing Businesses

It's 9 AM on Monday. An investor asks a simple question: what's our portfolio-wide occupancy this month?

You know the answer exists. It's just scattered across four different systems.

Property A is on Yardi. Properties B through F are on AppFolio. That acquisition from last year is still on the seller's MRI instance because migration keeps getting pushed back. And the two newest properties? Someone's tracking them in Excel until you figure out which system to put them on.

Getting a single number means logging into four platforms, exporting data, reconciling different date formats, and building a spreadsheet. By the time you have the answer, two hours have passed. The investor has moved on to other questions.

---

## The Multi-System Reality

Nobody plans to run their portfolio across four property management systems. It just happens.

You acquire a property that comes with an existing PM contract. The PM uses Yardi. You're not going to make them switch for one building. Six months later, you acquire three more properties from a different seller. They're on AppFolio. Same story.

Before long, your 15-property portfolio spans three systems, two Excel files, and someone's memory of what happened before 2020.

The fragmentation isn't laziness. Migration is expensive and risky. Moving a property from one system to another means re-entering lease data, re-training staff, and hoping nothing breaks during the transition. For a property you might sell in three years anyway, the math doesn't work.

So you live with fragmentation. And fragmentation lives with you, extracting a tax every time someone needs a portfolio-wide answer.

---

## What Fragmentation Actually Costs

The obvious cost is time. Every portfolio-level question requires manual consolidation. But the hidden costs run deeper.

**Delayed decisions.** When getting an answer takes two hours, you ask fewer questions. That property with creeping vacancy? You might not notice until it's a problem because checking requires effort.

**Stale data.** That consolidated spreadsheet you built last Tuesday? It's already wrong. Rent was collected Wednesday. A lease was signed Thursday. The spreadsheet doesn't know.

**Error accumulation.** Every manual consolidation introduces errors. Copy-paste mistakes. Formula problems. Unit mix-ups between systems that track square feet differently. Over time, you stop trusting your own reports.

**Reporting delays.** Quarterly investor reports become a two-week project because you're rebuilding everything from scratch. Your team dreads quarter-end.

One property manager we worked with estimated they spent 15 hours per week on data consolidation across 23 properties. That's nearly \$40,000 per year in labor cost, producing information that was outdated before anyone saw it.

---

## The Integration Alternative

The solution isn't forcing everything onto one system. It's connecting the systems you have.

Modern integration approaches pull data from multiple sources into a unified layer. Your team continues using Yardi, AppFolio, MRI, and whatever else makes sense for each property. But when you need a portfolio view, you look at a dashboard that shows everything together.

This isn't science fiction. Property management systems have APIs. They expose data through standard interfaces. A properly built integration reads from those interfaces on a schedule, transforms the data into a common format, and presents unified views.

The key word is "properly built." Bad integrations break constantly, require manual intervention, and create more problems than they solve. Good integrations run silently in the background, updating automatically, surfacing issues only when something actually needs attention.

---

## What Unified Visibility Looks Like

Imagine opening a single dashboard and seeing:

- Portfolio-wide occupancy, updated as of this morning
- NOI by property, with month-over-month and year-over-year comparisons
- Collections status across all properties, sorted by amount outstanding
- Lease expirations for the next 6 months, ranked by revenue impact
- Maintenance requests by property, with aging analysis

No logging into four systems. No Excel consolidation. No hoping the numbers are right.

When the investor asks about portfolio occupancy, you have the answer in 10 seconds. When you want to check on a specific property, you drill down into the detail. When you need to export for a board presentation, the data is already formatted.

This isn't about fancy technology. It's about having information when you need it instead of spending hours retrieving it.

---

## How It Actually Works

Building integrations used to require expensive custom development. That's changed.

Yardi, AppFolio, MRI, and most modern property management systems have built-in ways to share data with other systems. Some charge extra for it. Some include it in higher-tier plans. But the capability exists.

The connection pulls information from each of your systems on a schedule, makes all the data look the same regardless of where it came from, and feeds it into dashboards you can actually use.

For a 20-property portfolio across two or three systems, a competent implementation takes weeks, not months. The complexity scales with the number of systems and the depth of data you need, but this is well-established work.

---

## What You Actually Need to Track

Before building anything, define what matters. Not every data point deserves dashboard space.

For most property managers, the critical metrics fall into four categories:

**Occupancy and leasing:** Current occupancy by property and portfolio. Lease expirations by month. Time on market for vacant units. Lease renewal rates.

**Financial performance:** Gross revenue, operating expenses, NOI. Budget variance. Collections and delinquency. Year-over-year trends.

**Operations:** Open maintenance requests. Work order completion time. Vendor spend. Capital expenditure tracking.

**Tenant health:** Payment patterns. Lease compliance issues. Communication history. Renewal likelihood.

Start with the metrics you actually check weekly. Those deserve real-time visibility. Add complexity only when it serves a clear purpose.

---

## Implementation Without Disruption

The biggest fear with any technology project: what if it breaks what's already working?

Portfolio integration is read-only. You're extracting data from source systems, not writing to them. Your property managers continue their normal workflows in Yardi or AppFolio or whatever they use. The integration layer observes. It doesn't interfere.

This means zero disruption to daily operations. No retraining. No workflow changes. No migration risk. Your team keeps doing what they're doing. You just gain visibility into what they're doing.

The implementation process typically looks like this:

1. Inventory your current systems and identify API capabilities
2. Define priority metrics and reporting requirements
3. Build connections to each source system
4. Create the transformation layer that unifies data formats
5. Deploy dashboards and validate accuracy against source systems
6. Train users and establish update schedules

Most portfolios under 50 properties can complete this in 4-6 weeks. Larger portfolios or more complex requirements take longer, but the approach scales.

---

## The Cost Question

Integration projects range widely based on scope. A basic dashboard connecting two systems to show occupancy and collections might cost \$15,000-25,000. A full platform with deep financial integration, automated reporting, and advanced analytics might run \$50,000-100,000.

Compare that to the alternative: continuing to spend 15 hours per week on manual consolidation (\$40,000+ per year), making decisions on stale data, and scrambling every quarter to produce investor reports.

For most portfolios above 10 properties, the integration pays for itself within a year. Below that threshold, simpler solutions might make more sense. Above 30 properties, the question isn't whether to integrate but how quickly.

---

## Choosing an Approach

You have options for how to build portfolio visibility:

**Off-the-shelf platforms:** Companies like Prophia, Lessen, and others offer pre-built portfolio analytics. They handle integrations with common property management systems. Faster to deploy, but less customizable.

**Custom development:** Build exactly what you need with a development partner. More flexible, but requires more upfront investment and ongoing maintenance.

**Hybrid approach:** Use an off-the-shelf platform for standard integrations and layer custom reporting on top. Balances speed with flexibility.

The right choice depends on your specific systems, your reporting requirements, and whether you have internal technical resources. There's no universal answer.

---

## Your Data Stays Yours

Your portfolio data stays on your systems.

The integration reads from your property management software, but your occupancy numbers, NOI, and tenant information don't get shipped to some vendor's cloud. Your competitive information stays yours. Nobody else sees your portfolio performance or your investor reports.

This matters more than most people think until they think about it. Your deal pipeline, your tenant relationships, your financial performance. That's not information you want floating around on someone else's servers.

---

## Getting Started

You don't need to solve everything at once. Start with the pain point that costs you the most time.

If quarterly reporting is the bottleneck, build a financial consolidation dashboard first. Pull revenue and expense data from each system into a unified view. Get that working before adding complexity.

If occupancy tracking is the issue, start there. Connect lease data across systems. Build a single view of vacancies and upcoming expirations.

Each integration you build reduces manual work and proves the approach. Expand from there based on what delivers value.

The goal isn't perfect visibility into everything. It's having the answers you actually need, when you need them, without the spreadsheet gymnastics.
